

Homepage - index.html

Design Decisions:

- Use the F-pattern to draw attention to the WatchTower logo first, then the nav bar, then the main text
- “Catch all your errors in real time” is bolded and in larger text to draw attention to it first
- “Get started” button is clearly contrasted from the background, using the blue color to highlight its visual importance

Possible Changes:

- Signup and Login button in two different places creates redundancy
 - **Have “Get started” only below the “catch all your errors” and the login only in the nav bar**
 - Pros:
 - groups “Get started” with “catch all your errors” because both have a similar goal: To pull in new users.
 - Groups “login” with the nav bar, which is more likely the focal point for returning users that need the login button
 - Cons:
 - Splits the login and sign up buttons, which are similar functions. Possibly makes it more hard for users to find each
 - **Have both sign up and login only below the “catch all your errors”**
 - Pros:
 - Both buttons with similar functions are grouped together, making it easier for users to visually follow
 - Cons:
 - Nav bar becomes more sparse, reducing the need for it to be important in the visual hierarchy.
 - Possibly eliminates need to use F-pattern layout
 - **Leave as is**
 - Pros:
 - Requires less work and more time to focus on other MVP features
 - Nav bar doesn’t need to change for each different page of the website, creates predictability
 - Makes sense for the website and flow as a whole
 - Cons:
 - May not make as much sense for each individual page

Login - login.html

Design Decisions:

- Uses Z-pattern layout

- Nav bar is at the top to indicate visual importance with WatchTower logo at the top left so it's the first thing you see
- "Welcome back" is large and bold with lots of white space around it to draw attention
- The login has a slightly different color than the background to separate it as its own element.
- The login is large in scale with the rest of the website, denoting its importance
- Important buttons and text are blue to add contrast, which indicates importance

Signup - signup.html

Design Decisions:

- Same Z-pattern and layout as login to create predictability. Makes it easy for users to understand the layout

Possible Changes:

- Sign up box is not fully visible at initial page load. Need to scroll down
 - **Condense elements within to make it completely visible without scrolling**
 - Pros:
 - You will be able to see "create account" button from the start, which is a visually important element
 - Less work for the user
 - Allows user to see all elements on the page immediately
 - Cons:
 - May shrink the individual components too much, making it hard to read text
 - Reducing whitespace between elements may make it feel too cluttered
 - **Leave as is**
 - Pros:
 - Less work, allowing time for other MVP features
 - May not be that big of a deal to users
 - Cons:
 - May reduce user experience

Dashboard - dashboard.html

Design Decisions:

- The project selector is at the top because all the elements below are influenced by/conditional on which project is selected
 - **Associated User Stories:**

- As a developer I want to be able to monitor multiple projects and switch between them so that it's easy for me to simultaneously monitor those projects **(MVP)**
- Site status is next because we as a group decided that was the biggest part of our MVP and what our stakeholders wanted to see in our website
 - **Associated User Stories:**
 - As a user I would want a simple dashboard, with only a symbol telling me whether my site is down, with errors, or is up, with not a lot of clutter, in order to easily tell when my website is up **(MVP)**
- Next we have website metrics, which is next in importance in our MVP after site status
 - **Associated User Stories:**
 - As a user, I want a simple flow of the application, meaning I want a clear path to get my apps errors and not a lot of fluff in order to get straight to my metrics and errors **(MVP)**
 - As a developer, I want to monitor website uptime and service availability so that I can detect outages or inaccessible services and ensure the application remains operational for users. **(MVP)**
- After metrics, we have graphs and its associated options such as different charting options, and time range. These graphs are meant to give more in-depth info about each metric, which is why they are placed directly below the metrics
 - **Associated User Stories:**
 - As a user I would want to be able to change how my data is represented through different buttons that can switch between a bar chart line graph and then, customize which charts and widgets appear on my dashboard, tabular etc, in order to more suit my preferences on how I like seeing data. **(additional features)**
- Logs are last on the page because they have the most dense detail—so are the most cumbersome to read and understand for the user—, are probably looked at least often by users and thus has lower importance, and will be shown as data tables which are most visually cluttered. All these are reasons why we decided to put it at the bottom of the page. Researching other websites also shows a pattern of logs being placed at the bottom.
 - **Associated User Stories:**
 - As a developer I would want a widget with a log of different versions of my website and the uptime rate and number of bugs in order to assess which version of my app is most stable. **(additional features)**
 - As a developer who wants to be able to clearly trace the origin of errors, I would want metrics that capture the error origin in extreme detail, including the app version, timestamps, page that the error is from, etc. **(additional features)**

Possible Change - Nav Bar Options:

- **Horizontal along the top**
 - Pros:
 - Similar to layout of the rest of the pages

- Cons:
 - Reduces vertical space on page for most important elements (i.e. body of the dashboard)
 - Less elements of the dashboard can be seen at once since they are laid out vertically
 - There are many nav buttons, which leads to shrinking font size of/white space between buttons to fit them all horizontally in line
- **Vertical down the left side**
 - Pros:
 - Allows for more white space between buttons
 - Allows for larger font size for readability
 - Allows for more vertical space for dashboard
 - Cons:
 - Takes up more visual space in the page than horizontal or hidden options
- **Hidden in hamburger nav button**
 - Pros:
 - Can be used for both phone and computer layouts
 - Leaves most space for dashboard elements
 - Cons:
 - Puts buttons that users may use frequently behind another button, requiring more clicks on average for necessary functions
